salicylic acid in soil systems
using a combination of sorption
and diffusion: part II. Adsorption
Environmental Impact
Assessments, and in particular
the Scope 3 effects of EIA for
decision-making, have been
considered in recent years as
options to optimize forest
management. Optimized
planning can increase the
importance of ecological
benefits by reducing the
harvesting volume, or it can
avoid unnecessary harvesting,
particularly in cases where a

resulting reduction in stand density induces increases in edge effects and positive feedback to the above-ground biological and structural carbon cycle. These planning options have been mainly tested in orchard systems, and only limited studies have analyzed the transport properties in diverse forest stands. In this paper, the influence of hydrodynamics and chemical heterogeneity on the dispersion of dissolved salicylic acid (SA) in an undisturbed Douglas fir (*Pseudotsuga menziesii* (Mirb.) Franco) system was studied using flow-through experiments under controlled conditions. The results of the flow-through experiments were validated against standard field-based approaches for

assessing SA dispersion properties in soil systems, namely composting reactors and Solling functional units (SFU) systems. Five separate experiments were carried out to investigate the effects of temperature (13 and 20 degrees C), size of the drainage patch (24, 60 and 120 m(2)), and the effect of dendrochronological age of the stand in 82138339de
